

Only gradient methods predict what deleting training rows actually does

Setup: 13 ways of scoring which training rows cause the misalignment, tested causally: delete a scored group of 685 rows, retrain, measure the real change. Each panel: predicted effect (x) vs measured effect (y) for 10 groups. The 10 measured y-values are identical in every panel; only the method's prediction changes.

● B1-B4 random subsets ▲ T1-T3 top-ranked slices ▼ B1-B3 bottom-ranked slices
