

Gradients find the rows that cause the misalignment; the provenance labels do not

A · Which methods predict what deleting rows actually does

B · The winner's predictions vs the ten measured effects

Figure 4. A: rank correlation between each method's predicted effect of deleting a group of rows (the size of the 10% edit) and the effect measured after retraining without it, over ten groups; the preregistered bar is 0.5 to pass and 0.2 to fail. B: the winning method's predicted group effects against the ten measured changes in loss on 71 fixed misaligned answers.
